## A THEORETICAL STUDY OF PLANING CRAFT STABILITY

James R. McFarlane and Raymond N. Stoetzer

Submitted to the Department of Naval Architecture and Marine Engineering on 20 May, 1965 in partial fulfillment of the requirements for the degree of Naval Engineer and the degree of Master of Science in Naval Architecture and Marine Engineering.

### ABSTRACT

Dynamic instability of planing craft on calm water, porpoising, is a phenomenon which has not been properly understood. Empirical relations are available for predicting the regime of stability. The relations, when compared, lead to conflicting design requirements to increase stability.

It is therefore desirable to develop a theoretical approach to the problem so that the effects of beam, deadrise angle, etc. on stability can be studied.

The results of the investigation imply that a decrease in deadrise angle, a decrease in beam and an increase in distance from LCG to transom result in an increase in stability. Changes in shaft angle and vertical height of the center of gravity and moment of inertia have very little effect on the stability of a boat while it is planing. However further investigation is required to verify these results.

In conjunction with this paper, a computer program was written which can be used in the design of planing craft to predict boat attitude, wetted surface area, drag and effective horse power. This program will be available for use in the XIII Department library.

A THEORETICAL STUDY OF PLACING CRAPT STABILITY

James R. Moxley, and Professor M. Moxley

Submitted to the Department of Naval Architecture and Marine Engineering on 10 May, 1964 in partial fulfillment of the requirements for the degree of Naval Engineer and the degree of Master of Science in Naval Architecture and Marine Engineering.

ABSTRACT

Dynamic instability of placing craft on calm water, porpoising, is a phenomenon which has not been properly understood. Empirical relations are available for predicting the regime of stability. The relations, when compared, lead to conflicting design requirements to increase stability.

It is therefore desirable to develop a theoretical approach to the problem so that the effects of beam, draft angle, etc. on stability can be studied.

The results of the investigation imply that a decrease in draft, a decrease in beam and an increase in distance from LCZ to transom result in an increase in stability. Changes in draft angle and vertical height of the center of gravity and moment of inertia have very little effect on the stability of a boat while it is planing. However, further investigation is required to verify these results.

In conjunction with this paper, a computer program was written which can be used in the design of placing craft to predict boat attitude, wetted surface area, drag and effective horsepower. This program will be available for use in the XII Department library.

## I. INTRODUCTION

The unstable motions of planing craft have been under study for many years and have been the subject of much literature (see bibliography). The ability to be able to predict the stability characteristics of a particular hull in the early stages of design is of importance to naval architects. A knowledge of the effects of variables such as beam, deadrise angle, etc. on stability would permit intelligent corrective action to be taken to increase the dynamic stability of existing craft.

The problem of planing craft stability involves many variables and empirical relations between some of the design variables have been developed to predict dynamic stability.

Two formulae recently developed empirically from experimental data, (2) and (12), result in conflicting design requirements to increase stability (see Appendix C). It is therefore desirable to develop a theoretical approach to the problem so that the effects of design variables can be determined independently of experimental data.

Perring (10) attempted a theoretical approach. His lack of success can be attributed to a number of causes. The foremost of these being lack of sufficient experimental and theoretical information to predict the stability derivatives accurately and the omission of important terms.

1. INTRODUCTION

The unstable motion of flying craft have been under study for many years and have been the subject of much literature (see Bibliography). The ability to be able to predict the stability characteristics of a particular craft in the early stages of design is of importance to naval architects. A knowledge of the effects of variables such as beam, deadrise angle, etc. on stability would permit intelligent corrective action to be taken to increase the dynamic stability of existing craft.

The problem of predicting craft stability involves many variables and empirical relations between some of the design variables have been developed to predict dynamic stability.

Two formulas recently developed empirically from experimental data, (1) and (2), result in conflicting design requirements to increase stability (see Appendix C). It is therefore desirable to develop a theoretical approach to the problem so that the effects of design variables can be determined independently of experimental data.

Ferrary (10) attempted a theoretical approach. His lack of success can be attributed to a number of causes. The foremost of these being lack of sufficient experimental and theoretical information to predict the stability derivatives accurately and the omission of important terms.

## II. THEORY

A planing hull, as a rigid body, has six degrees of freedom. This study treats the boat as a two degree of freedom system by investigating what is considered to be the most important motions, heave in the Z-direction and pitch about the Y-axis.

The equations of motion are nonlinear. To facilitate the solution of these equations it is necessary to linearize them.

Linearized equations of motion for ships have been developed by Abkowitz (1), Korvin-Korvosky (7) and others. Those of Abkowitz are most complete. If the coefficients, i. e. stability derivatives, are substituted into these equations and then the result transformed into the frequency domain, it should be possible to evaluate the stability by using the Routh criterion. (5).

The method used to predict stability or lack thereof proceeds as follows:

1. The stability derivatives are determined, see Appendix A.
2. The stability derivatives are substituted into the linearized equations for ship motion. (1)
3. The resulting equations are transformed by substitutions of the form  $z = Z_{\max} e^{st}$  and  $\theta = \theta_{\max} e^{st}$ .
4. An equation in S is obtained.
5. The Routh discriminant is evaluated for the fourth order equation in S, see Appendix A.

II. THEORY

A plumb line in a right body has six degrees of freedom. This study treats the first two degrees of freedom by investigating the motion of the plumb line in the most important direction, that is the Z-direction and gives about the Y-axis.

The equations of motion are nonlinear. To facilitate the solution of these equations it is necessary to linearize them.

Linearized equations of motion for ships have been developed by Akiwits (1), Kozin-Kozovsky (2) and others. These equations are most complete. If the coefficients, i. e. stability derivatives, are substituted into these equations and then the result transformed into the frequency domain, it should be possible to evaluate the stability by using the Routh criterion (3).

The method used to predict stability of the linearized equations is as follows:

1. The stability derivatives are determined, see Appendix A.
2. The stability derivatives are substituted into the linearized equations for ship motion (4).
3. The resulting equations are transformed by substitution of the form  $s = \sigma + j\omega$  and  $\theta = \theta_{max} e^{j\omega t}$ .
4. An equation in  $\sigma$  is obtained.
5. The Routh discriminant is evaluated for the fourth order equation in  $\sigma$ , see Appendix A.

### III. DESCRIPTION OF WORK ACCOMPLISHED

The first step toward a solution was to determine the stability derivatives and combine them to form the coefficients of the linearized equations of motion, see Appendix A. The coefficients were then non-dimensionalized using beam as the non-dimensionalizing length (12).

A computer program was written to solve for the Routh discriminants, see Appendix H, using as input data the results from a series of tests run at the David Taylor Model Basin (2), see Table 3. The resulting discriminants were then plotted against speed showing a consistency in the directions of the paths, however there was no obvious difference between stable and unstable<sup>1</sup> boats, see Figure 9.

At this point, an attempt was made to determine the roots of the fourth order stability equation to examine their loci using a computer program from the MIT "SHARE" library. (SHARE No. 1514 RTSCH). RTSCH proved to be unsatisfactory. The answers obtained from this program are seriously in error even for the simplest of input equations.

It was then decided to vary in turn what seemed to be the most important variables: DIFB1, DIFC1, B2, D1, D2, E1, G1, and G2. This was done to determine the effect of changes in their magnitude on the Routh discriminant. From Figure 10 it can be seen that varying G2 roughly grouped the stable and unstable boats with the unstable group centered about  $G2$  equal to  $0.38 \times G2$  at the point of zero Routh discriminant. The program was then run with  $G2$  equal to  $0.38 \times G2$  so that the loci of the discriminants could be examined. The results are shown in Figure 11. Based on these results it was decided to in-

---

1. Unstable boats, as referred to in this paper, are those which porpoised at a  $F_{\nabla}$  less than 6.0. Stable boats are those which had not porpoised before maximum test speed (2) was attained ( $F_{\nabla} = 6.0$ ).

IV. DESCRIPTION OF WORK ACCOMPLISHED

The first two parts of the solution were to determine the stability of the system and to determine the coefficients of the characteristic equation of motion. The coefficients were then determined by using the method of residues (12).

A computer program was written to solve for the roots of the characteristic equation. The program is listed in Appendix B. The results of the program are given in Table 1. The results show that the roots of the characteristic equation are all in the left half plane, indicating that the system is stable. However, there was an interesting difference between the stable and unstable roots, see Figure 9.

At this point, an attempt was made to determine the roots of the fourth order stability equation by solving their fact using a computer program from the MIT "SHARE" library (SHARE No. 1814 STCH). This program proved to be unsatisfactory. The answers obtained from this program are seriously in error even for the simplest of input equations.

It was then decided to vary in turn what seemed to be the most important variables:  $\epsilon$ ,  $\delta$ ,  $\eta$ ,  $\zeta$ ,  $\xi$ ,  $\theta$ ,  $\phi$ ,  $\psi$ , and  $\omega$ . This was done to determine the effect of changes in their magnitudes on the root distribution. From Figure 10 it can be seen that varying the roughly groups the stable and unstable roots with the unstable group centered about  $\sigma = 0.38 \times G2$  and  $\omega = 0.38 \times G2$ . The program was then run with  $G2$  equal to  $0.38 \times G2$ . The results show that the fact of the distribution could be examined. The results are shown in Figure 11. Based on these results it was decided to vary

1. Unstable roots, as referred to in this paper, are those which possessed a  $\sigma$  less than 0. Stable roots are those which had not possessed before maximum test speed ( $\sigma = 0$ ).

investigate G2 further. Since the term G2 is made up of two parts, force  $\times \frac{\partial(\text{arm})}{\partial z} + \text{arm} \times \frac{\partial(\text{force})}{\partial z}$ , it was decided to vary these two parts independently to see if better correlation could be achieved in either of the two groups.<sup>1</sup> Correlation was not improved, see Figures 12 through 17. However it was observed that the discriminants for the stable boats changed very little with changes in G2, or its parts. On the other hand the discriminants of the unstable boats changed a great deal with changes in G2. This lead to the conclusion that there must be a term in the coefficients of the characteristic equation which over-powered G2 when the boat was stable but was of the same magnitude as G2 when the boat was unstable.

Based on information obtained thus far, it was decided to investigate each term of the Routh discriminant to see which of the coefficients were controlling for the stable and unstable boats. Values of the coefficients obtained from program 1 in Appendix H were inserted into each term manually and inspection of the results was unfruitful. No obvious difference could be detected between stable and unstable boats. It was concluded that the interaction was much more subtle.

A closer inspection of each term indicated that the coefficients  $Z_q$  and  $M_w$ , D1 and D2, may interact with important effects and this became the final step in the investigation of the coefficients. The results are shown in Figures 18 through 20. At this point the investigation of the coefficients of the equations of motion was terminated because of time

---

1. At this point it was necessary to reduce the number of plots to three stable and three unstable boats in order both to simplify the plots and to make more efficient use of computer time. The unstable boats were selected by choosing two which had axis intercepts fairly close together and third whose intercept was remote from these (models 4665-3, 4666-13, and 4668-9 in Figure 10).

verify the results. Since the term  $Q_2$  is made up of two parts,  $Q_{2a}$  and  $Q_{2b}$ , it was decided to vary these two parts independently to see if better correlation could be achieved in either of the two groups. <sup>1</sup> Correlation was not improved, see Figure 13 through 17. However it was observed that the discriminants for the stable boats changed very little with change in  $Q_2$ , or its parts. On the other hand the discriminants of the unstable boats changed a great deal with change in  $Q_2$ . This lead to the conclusion that there must be a term in the coefficients of the characteristic equation which overpowered  $Q_2$  when the boat was stable but was of the same magnitude as  $Q_2$  when the boat was unstable.

Based on information obtained thus far, it was decided to investigate each term of the Roth discriminant to see which of the coefficients were controlling for the stable and unstable boats. Values of the coefficients obtained from program 1 in Appendix H were inserted into each term manually and inspection of the results was unfruitful. No obvious difference could be detected between stable and unstable boats. It was concluded that the interaction was much more subtle.

A closer inspection of each term indicated that the coefficients  $Z_p$  and  $M_w$ ,  $D_1$  and  $D_2$ , may interact with important effects and this became the final step in the investigation of the coefficients. The results are shown in Figures 18 through 20. At this point the investigation of the coefficients of the equations of motion was terminated because of time

1. At this point it was necessary to reduce the number of plots to three stable and three unstable boats in order both to simplify the plots and to make more efficient use of computer time. The unstable boats were selected by choosing two which had zero intercepts fairly close together and three whose intercept was remote from these (models 4663-3, 4663-12, and 4663-9 in Figure 10).

limitations.

Concurrently with the above work, a program was written to solve for all the hydrodynamic performance characteristics of the planing hull: planing angle, wetted surface, resistance, power requirements, and stability. This program uses design parameters as inputs and provides an easily readable output. Development of the criterion for the equilibrium planing condition is shown in Appendix E and details of the program are contained in Appendix H. In order to facilitate the writing of this program, it was necessary to determine an expression for mean bottom velocity based on an empirical function of deadrise angle, Appendix D.

The coefficients of the equations of motion and the Routh discriminant based on the computed planing conditions were compared with those based on experimental data. The result of this comparison is shown in Table 2.

The program was then run, for model 4668-9 with  $G_2$  equal to  $0.38 \times G_2$ , varying  $BETA_1$ ,  $EPSILI$ ,  $VCG$ ,  $BEAM$ ,  $CG$ , and  $YI$  in turn. The results were then plotted, Figure 21, so that a comparison of the relative effects of the variables could be made.

limitation.

Consequently, with the above work, a program was written to solve for all the hydrodynamic performance characteristics of the planing hull: trim angle, wetted surface resistance, power requirements, and stability. This program uses design parameters as inputs and provides an easily readable output. Development of the criterion for the equilibrium planing condition is shown in Appendix B and details of the program are contained in Appendix H. In order to facilitate the writing of this program, it was necessary to determine an expression for mean bottom velocity based on an empirical function of loadline angle, Appendix E.

The coefficients of the equations of motion and the body characteristic based on the computed planing conditions were compared with those based on experimental data. The result of this comparison is shown in Table 2.

The program was then run, for model 1888-9 with  $L/D$  equal to 0.35, varying  $B/D$ ,  $B/D^2$ ,  $B/D^3$ ,  $B/D^4$ ,  $B/D^5$ , and  $B/D^6$  in turn. The results were then plotted, Figure 2, so that a comparison of the relative effects of the variables could be made.

#### IV. DISCUSSION OF RESULTS

The plots of the discriminant versus speed obtained from the first calculations, Figure 9, are disappointing. According to these results most models were stable throughout the entire range of speeds investigated, contrary to the experimental results. The lack of agreement could be caused by one, or both, of the following:

- (a) incorrect formulation of one or more of the stability derivatives
- (b) neglecting the cross coupling effects of longitudinal motion.

Perring (10) indicated that inclusion of the longitudinal motion cross coupling effects had negligible effect on the outcome of his solution to the problem. It is possible that in the present, more refined solution, the magnitude of this cross coupling may become relevant.

The investigation of the effects of varying the magnitudes of the stability derivatives indicates that a solution to the problem may lie in this area. Although variations in  $Z_w$ ,  $Z_z$ , and  $(Z_\theta + u_0 Z_w)$ , DIFB1, DIFC1, and G1, failed to yield any evidence of consistent influence, Figure 10 shows that variation of G2 produced a fairly consistent difference between stable and unstable boats. It is true that there is considerable scatter of the axis intercepts within each group, but there is an undeniable consistency in the grouping. It is also of interest to note there is much less scatter in the stable group than in the unstable group. The grouping of the stable boats cannot be attributed to their equal Froude number. An examination of the unstable boat grouping, Figure 10, indicates that models 4665-3 and 4668-9 intercept the axis at the same point with  $F_\nabla$  of 3.24 and 5.03 respectively whereas model 4666-17, which has a  $F_\nabla$  of 5.01 (essentially equal to that of model 4668-9), has an intersection remote from the preceding two.

The investigation of the loci of the discriminants with G2 equal to  $0.38 \times G2$ , Figure 11, show that the original curves, shown in Figure 9,

The plots of the discriminant versus speed obtained from the first calculations, Figure 9, are disappointing. According to these results most models were stable throughout the entire range of speeds investigated, contrary to the experimental results. The fact of agreement could be caused by one, or both, of the following:

- (a) incorrect formulation of one or more of the stability derivatives
- (b) neglecting the cross coupling effects of longitudinal motion.

Figure 10 indicates that inclusion of the longitudinal motion cross coupling effects had negligible effect on the outcome of the solution to the problem. It is possible that in the present, more refined solution, the magnitude of this cross coupling may become relevant.

The investigation of the effects of varying the magnitudes of the stability derivatives indicates that a solution to the problem may be found in this case. Although variations in  $Z_w$ ,  $Z_u$ , and  $(Z_\theta + u_z Z_w)$ , DIFB1, DIFB1, and G1, failed to yield any evidence of constant influence, Figure 10 shows that variation of G2 produced a fairly consistent difference between stable and unstable bores. It is true that there is considerable scatter of the axis intercepts within each group, but there is an undeniable consistency in the grouping. It is also of interest to note there is much less scatter in the stable group than in the unstable group. The grouping of the stable bores cannot be attributed to their equal Froude number. An examination of the unstable bore grouping, Figure 10, indicates that models 4888-3 and 4888-5 intercept the axis at the same point with  $F_v$  of 3.24 and 6.03 respectively whereas model 4888-11, which has a  $F_v$  of 6.01 (essentially equal to that of model 4888-5), has an intersection remote from the preceding two.

The investigation of the loci of the discriminants with G2 equal to 0.38 x G1, Figure 11, show that the original curves, shown in Figure 9,

now bend down toward negative values of discriminants as speed increases. Some of the unstable models have loci consistent with experimental data, i. e. the Routh discriminant heads toward negative values as the porpoising speed is approached however, the boats which were stable throughout their test range have loci lying completely below the axis (negative discriminants indicate instability). This indicates that simply multiplying  $G_2$  by a single factor does not produce reliable Routh discriminants.

The investigation of the effects of varying the two components of  $G_2$  separately, Figures 12 through 17, although not producing better correlation within the stable or unstable groups does point out the small effect that these variations have on the intercepts of the stable group compared to their effect on the unstable boats. This information, as it stands, indicates that other terms in the equations of motion are more powerful at stable speeds but that, at the porpoising speed,  $G_2$  is a powerful term.

The results of the investigation of the simultaneous variations of  $D_1$  and  $D_2$ , see Figures 18 through 20, point the way to what may be a valuable area for further study. The first useful bit of information obtained is the fact that  $Z_{\dot{q}}$ ,  $D_1$ , has very little effect on the magnitude of the Routh discriminant and that  $M_w$ ,  $D_2$ , has a large effect. The most important result of this investigation is the fact that the axis intercepts of models 4666-13 and 4668-9 have been reversed in their relative positions from what they were when the coefficient  $G_2$  was varied. This means that a simultaneous variation of  $D_2$  and  $G_2$  may cause these two extreme boats to cross the axis at the same point and thereby correlate the unstable group.

Correlating the results in this manner does not really solve the problem. The stability indicator, Routh discriminant, is not reliable, as the discussion of Figure 11, Appendix F, has shown. Further work is

not be of lower level negative values of discriminants as found for  
 crossers. Some of the unstable models have not contained any  
 particular data, i.e. the South discriminant needs forward negative  
 values at the corresponding speed in approaching however, the data which  
 were stable throughout their test runs have not being completely below  
 the axis (negative discriminants indicate instability). This indicates  
 that simply multiplying G2 by a single factor does not produce reliable  
 North discriminants.

The investigation of the effects of varying the two components of G2  
 separately, Figures 12 through 17, although not producing better corre-  
 lation within the stable or unstable groups does point out the small ef-  
 fect that these variations have on the intercepts of the stable group  
 compared to their effect on the unstable boats. This information, as  
 it stands, indicates that other terms in the equations of motion are  
 more powerful at stable speeds but that, at the corresponding speed, G2  
 is a powerful term.

The results of the investigation of the simultaneous variations of D1  
 and D2, see Figures 18 through 20, point in a way to what may be a  
 valuable area for further study. The first useful bit of information ob-  
 tained is the fact that  $D_1$  has very little effect on the magnitude  
 of the North discriminant and that  $D_2$  has a large effect. The  
 most important result of this investigation is the fact that the axis in-  
 tercepts of models 422-15 and 428-1 have been reversed in their  
 relative positions from what they were when the coefficient G2 was  
 varied. This means that a simultaneous variation of D1 and D2 may  
 cause these two extreme boats to cross the axis at the same point and  
 thereby correlate the unstable group.

Correlating the results in this manner does not really solve the  
 problem. The stability indicator, North discriminant, is not reliable,  
 as the discussion of Figure 11, Appendix F has shown. Further work is

required to produce better agreement between the intercepts of the discriminants and experimental data. An experimental investigation of the individual stability derivatives for comparison with the theoretically developed derivatives would be helpful in locating the terms of the equations of motion which need to be reevaluated.

The program, which solves for the hydrodynamic performance characteristics of planing boats, yields information of importance to design.

Starting with attitude, wetted keel length, wetted chine length, and drag, it can be seen, Table 1, that there is good agreement between theory and experiment for boat attitude and drag. The theoretical values of wetted keel length and wetted chine length are larger than the experimental values.

A plot of  $\frac{WKEEL - WCHINE}{b}$  vs TRIM comparing theory (12) and values calculated from the experimental results of (2), Figure 22, indicates that the mean line of data points lies above the theoretical line for this group of boats, Table 3. The largest errors occur at the largest angles of attack.

The expression developed for mean bottom velocity, Appendix D, yields results which compare very accurately with graphs shown in Figure 7.

The comparison of derivatives calculated directly from the program shows good agreement with the exception of C2 and E2, see Table 2. This error was most likely caused by the difference in actual and calculated wetted length.

The results of the variation of BETAI, EPSILI, BEAM, YI and CG, shown on Figure 21, can not be conclusive because of inconsistencies which have been found in the discriminant. However Figure 21 does show that the beam, deadrise angle and longitudinal position of the center of

required to produce better agreement between the theoretical and the  
discrepancies and experimental data. An experimental investigation  
of the individual stability characteristics for comparison with the theory  
could be developed. However, it would be helpful in locating the cause of the  
discrepancy if a method which could be revealed.

The program which solves for the hydrodynamic performance  
characteristics of planing boats, yields information of importance to  
design.

Starting with attitude, wetted hull length, wetted chine length, and  
drag, it can be seen, Table I, that there is good agreement between  
theory and experiment for boat attitude and drag. The theoretical values  
of wetted hull length and wetted chine length are larger than the ex-  
perimental values.

A plot of  $W_{REL} - W_{THEO}$  vs TRIM comparing theory (1) and  
values calculated from the experimental results of (2), Figure 2, in-  
dicates that the mean line of data points lies above the theoretical line  
for this group of boats. Table 2. The largest errors occur at the largest  
values of speed.

The expression developed for mean bottom velocity, Appendix D,  
yields results which compare very accurately with graphs shown in  
Figure 7.

The comparison of derivatives calculated directly from the program  
shows good agreement with the exception of C1 and E1, see Table 3.  
This error was most likely caused by the difference in actual and  
calculated wetted length.

The results of the variation of BETA, BETA1, BETA2, BETA3, BETA4, BETA5, BETA6, BETA7, BETA8, BETA9, BETA10, BETA11 and C1,  
shown in Figure 8, can not be observed because of inaccuracies  
which have been found in the discriminant. However, Figure 8 does show  
that the beam, deadrise angle and longitudinal position of the center of

gravity have the largest effect on stability. The implication of Figure 21 that a decrease in beam increases stability agrees with (12). The inference that an increase in deadrise angle results in a decrease in stability is, at first glance, distressing. However an inspection of Figure 16 of reference (12) indicates that this may well be the case for the boat examined. An increase in deadrise angle results in an increase in trim and a decrease in the lift coefficient. Both of the latter effects are destabilizing. If the destabilizing influence caused by the change of trim and of the lift coefficient is greater than the stabilizing effect of the increase in deadrise angle, the boat will be destabilized.

The results indicate that moving the center of gravity forward increases the range of stability. This forward movement results in a decrease in trim and it is known that a decrease in trim results in an increase in the range of stability.

greatly have the largest effect on stability. The application of Figure 21  
 that a decrease in beam increases stability except when (12). The in-  
 crease that an increase in deck angle results in a decrease in  
 stability is, in fact, almost negligible. However, an increase in  
 Figure 19 of reference (12) indicates that this may not be the case  
 for the boat examined. An increase in deck angle results in an in-  
 crease in trim and a decrease in the lift coefficient. Both of the latter  
 effects are destabilizing. If the destabilizing influence caused by the  
 change of trim and of the lift coefficient is greater than the stabilizing  
 effect of the increase in deck angle, the boat will be destabilized.  
 The results indicate that moving the center of gravity forward in-  
 creases the range of stability. This forward movement results in a  
 decrease in trim and it is known that a decrease in trim results in an  
 increase in the range of stability.

## V. CONCLUSIONS

Unfortunately this thesis does not go far enough to solve the problem of predicting the stability characteristics of a planing craft in the design stage. The relative magnitudes of the force and moment derivatives which make up the coefficients of the equations of motion give rise to inconsistencies in predicting stability which have not been resolved.

This study does indicate however that variations in the following quantities have a minor effect on the magnitude of the stability indicator (Routh discriminant):

- (a) change in lift coefficient x area with respect to vertical velocity (DIFB1)
- (b) change in lift coefficient x area with respect to vertical position (DIFC1)
- (c) change in vertical force with respect to the angular acceleration about the pitch axis ( $Z_{\dot{q}}$  or D1)
- (d) change in vertical force with respect to the angular velocity about the pitch axis ( $Z_{\dot{q}} + u_0 \cdot \text{VERM}$  or E1)
- (e) change in vertical force with respect to trim ( $Z_{\theta} + u_0 \cdot Z_w$  or G1)
- (f) change in pitching moment with respect to velocity in the heave direction ( $M_{\dot{q}} + u_0 \cdot M_w$  or B2)

and that the following have a major effect:

- (a) change in pitching moment with respect to vertical acceleration ( $M_{\ddot{w}}$  or D2)
- (b) change in pitching moment with respect to vertical position ( $M_z$  or G2).

The computer program, developed as part of this thesis, which solves for the other hydrodynamic performance characteristics of planing craft is able to reproduce experimental results with minor limitations. The expressions used in computing wetted length of chine and keel do not

Unfortunately this issue does not go far enough to solve the problem of predicting the stability characteristics of a planing craft in the sea-  
sign alone. The relative magnitudes of the force and moment derivatives  
which make up the coefficient of the equations of motion give rise to  
instabilities in predicting stability which have not been resolved.

This study does indicate however that variations in the following  
quantities have a minor effect on the magnitude of the stability in-  
dicator (Routh discriminant):

- (a) change in lift coefficient  $C_L$  area with respect to vertical velocity  
(DIPB)
  - (b) change in lift coefficient  $C_L$  area with respect to vertical position  
(LIPC)
  - (c) change in vertical force with respect to the angular acceleration  
about the pitch axis ( $\dot{\alpha}$  or D1)
  - (d) change in vertical force with respect to the angular velocity about  
the pitch axis ( $\dot{\alpha} + \alpha$ , VIRM or D1)
  - (e) change in vertical force with respect to trim ( $\alpha + \alpha_0$ ,  $\alpha_0$  or D1)
  - (f) change in pitching moment with respect to velocity in the heave  
direction ( $M_{\dot{w}} + \alpha_0 M_{\dot{w}}$  or B2)
- and that the following have a major effect:

- (a) change in pitching moment with respect to vertical acceleration  
( $M_{\ddot{w}}$  or D2)
- (b) change in pitching moment with respect to vertical position  
( $M_{\dot{w}}$  or D2)

The computer program, developed as part of this thesis, which solves  
for the other hydrodynamic performance characteristics of planing craft  
is able to reproduce experimental results with minor deviations. The  
expressions used in computing wetted length of chine and keel do not

yield accurate results. This causes an error in wetted length and aspect ratio which is further reflected in some of the coefficients of the motion equations.

The expression developed for computing the mean bottom velocity yields consistently good results.

The results of the study of the variations of design parameters generated by means of computer Program 2, Figure 21, show that the range of stability may be increased by decreasing deadrise angle, decreasing beam and moving the center of gravity forward. Changes in the vertical center of gravity, moment of inertia and shaft angle have minor effects on the range of stability.

In spite of the inconclusive results of the stability investigation, there is substantial indication that the stability problem can be solved. The solution of this problem will utilize results like those shown in Figure 21 in conjunction with Program 2. This should provide an extremely useful design tool for optimizing planing craft design. For example; assume that it is desired to design a planing hull to operate at 40 knots. The design procedure would proceed along the following lines:

- (a) Run computer Program 2 for a number of combinations of beam, deadrise angle, and the longitudinal position of the center of gravity obtaining drag information for all combinations which yield designs stable to 40 knots.
- (b) From the data thus obtained, develop a family of curves for each deadrise angle by plotting drag versus beam for several locations of center of gravity.
- (c) Choose the design for minimum drag for a 40 knot planing hull from the curves.

This method results. This method is used to find the best  
design which is better defined in terms of the coefficient of  
the roller bearings.

The method is developed for computing the best design velocity  
yields consistently good results.

The results of the study of the variations of design parameters  
generated by means of a computer program 2, Figure 2, show that the  
range of stability may be increased by increasing the roller angle, de-  
creasing the roller and moving the center of gravity forward. Changes in  
the vertical center of gravity, moment of inertia and roller angle have  
minor effects on the range of stability.

In spite of the extensive search in the stability investigation there  
is substantial indication that the stability problem can be solved. The  
solution of this problem will yield results like those shown in Figure  
21 in conjunction with Figure 2. This should provide an extremely  
useful design tool for optimizing bearing design. For example,  
assume that it is desired to design a bearing that is optimal at all times.  
The design procedure would proceed along the following lines:

- (a) Run computer Program 2 for a number of combinations of bearing  
designer angle, and the longitudinal position of the center of gravity  
obtaining design information for all combinations which yield designs  
stable to 50 knots.
- (b) From the data thus obtained, develop a family of curves for each  
designer angle by plotting design velocity versus bearing designer angle  
of center of gravity.
- (c) Choose the design for minimum drag for a 50 knot planing hull from  
the curves.

## VI. RECOMMENDATIONS

1. Repeat the study described herein using three degrees of freedom: pitch, heave, and surge.
2. Develop a more accurate method of predicting wetted length of keel and wetted length <sup>of chine</sup> for a planing surface with deadrise angle based on experimental data.
3. Make an experimental investigation of the force and moment derivatives for comparison with those developed theoretically.
4. An examination of the loci of the roots of the characteristic equation in the S-plane would produce valuable results once the inconsistencies in predicting stability are ironed out. An investigation of this sort would show the effect that variations in design parameters have on how the roots approach and cross the imaginary axis. This requires a more accurate root extraction computer program than was available to the authors.

VI. FUTURE RESEARCH

1. Develop the early detection device using laser beams of various  
width, beam, and surge.

2. Develop a more accurate method of predicting water depth of  
land and water height for a planting surface with various angles based  
on experimental data.

3. Make an experimental investigation of the force and pressure  
differences for comparison with those developed theoretically.

4. An examination of the force of the characteristic pressure  
in the 3-plane would produce valuable results since the instantaneous  
in producing a highly accurate soil. An investigation of this soil would  
show the effect that variations in design parameters have on how the  
roots approach and cross the imaginary axis. This requires a more  
sensitive root detection computer program than was available to the  
author.

APPENDIX A

Equations representing force and moment equilibrium for a ship can be expressed in the form: (1)

$$A1Z + B1\theta + C1Z + D1\theta + E1\theta + G1\theta = Fe^{i\omega t} \dots \text{forces}$$

$$A2\theta + B2\theta + C2\theta + D2Z + E2Z + G2Z = Me^{i\omega t} \dots \text{moments}$$

For the case under consideration here, smooth water, there are no external excitations. Therefore  $Fe^{i\omega t}$  and  $Me^{i\omega t}$  are both equal to zero.

By substituting the transforms  $Ze^{st}$  and  $\theta e^{st}$  into the force and moment equations we can obtain a characteristic equation of the form:

$$AA.S^4 + BB.S^3 + CC.S^2 + DD.S + EE = 0$$

Where:

$$AA = 1.$$

$$BB = \frac{A22.B11 + A11.B22 - D22.E11 - E22.D11}{A11.A22 - D11.D22}$$

$$CC = \frac{A22.C11 + B22.B11 + A11.C22 - D22.G11 - E22.E11 - G22.D11}{A11.A22 - D11.D22}$$

$$DD = \frac{B22.C11 + B11.C22 - E22.G11 - G22.E11}{A11.A22 - D11.D22}$$

$$EE = \frac{C22.C11 - G22.G11}{A11.A22 - D11.D22}$$

If the Routh criterion is applied to the characteristic equation it should be possible to evaluate the stability of the boat (5). The criterion indicates that a boat will be stable and nonoscillatory in the steady state if:

$$BB.CC.DD - AA.DD^2 - BB^2.EE > 0$$

Negative Routh discriminants are not meaningful for the case under study. Negative roots denote instability, instability implies motion, and motion in this case implies nonlinearity. Since the method is based on linearized equations, the last meaningful Routh discriminant is zero.

be expressed in the form (1)

$$\begin{aligned}
 A_1 \dot{x} + A_2 x + A_3 \dot{y} + A_4 y + A_5 \dot{z} + A_6 z &= M_1 \dot{x} + M_2 x + M_3 \dot{y} + M_4 y + M_5 \dot{z} + M_6 z \\
 A_7 \dot{x} + A_8 x + A_9 \dot{y} + A_{10} y + A_{11} \dot{z} + A_{12} z &= M_7 \dot{x} + M_8 x + M_9 \dot{y} + M_{10} y + M_{11} \dot{z} + M_{12} z
 \end{aligned}$$

For the case under consideration here, smooth water, there are no external excitations. Therefore  $M_1, M_2, M_3, M_4, M_5, M_6, M_7, M_8, M_9, M_{10}, M_{11}, M_{12}$  are all equal to zero.

By substituting the trial solution  $x = e^{st}$  and  $y = e^{st}$  into the above and simplifying we can obtain a characteristic equation of the form:

$$A A^2 + B B^2 + C C^2 + D D^2 + E E^2 = 0$$

where:  
 $A = 1$

$$B = \frac{A_{11} A_{12} + A_{12} A_{11} - A_{11} A_{12} - A_{12} A_{11}}{A_{11} A_{12} - A_{11} A_{12}}$$

$$C = \frac{A_{13} A_{14} + A_{14} A_{13} + A_{15} A_{16} + A_{16} A_{15} - A_{13} A_{14} - A_{14} A_{13} - A_{15} A_{16} - A_{16} A_{15}}{A_{13} A_{14} - A_{13} A_{14}}$$

$$D = \frac{A_{17} A_{18} + A_{18} A_{17} - A_{17} A_{18} - A_{18} A_{17}}{A_{17} A_{18} - A_{17} A_{18}}$$

$$E = \frac{A_{19} A_{20} - A_{19} A_{20}}{A_{19} A_{20} - A_{19} A_{20}}$$

If the Hurwitz criterion is applied to the characteristic equation it should be possible to evaluate the stability of the post (5). The criterion indicates that a post will be stable and nonoscillatory in the steady state if:

$$B B^2 C C^2 D D^2 - A A^2 D D^2 - B B^2 E E^2 > 0$$

Negative Hurwitz discriminants are not meaningful for the case under study. Negative roots denote instability, instability implies motion, and motion in this case implies instability. Since the method is based on linearized equations, the last meaningful Hurwitz discriminant is zero.

THE DERIVATION OF COEFFICIENTS FOR FORCE AND MOMENT EQUATIONS:

A1

A1 and A2 will have to have terms containing added mass and added inertia respectively. \* This is necessary because the added mass and added inertia may be of the same order of magnitude as that of the boat itself.

$$A1 = W + VERM$$

B1

$$B1 = Z_w$$

$$Z_w = \frac{\partial Z}{\partial w} = \frac{\partial \theta}{\partial w} \cdot \frac{\partial Z}{\partial \theta}$$

$$\frac{\partial \theta}{\partial w} = \frac{1}{V}$$

$$\frac{\partial Z}{\partial \theta} = \frac{1}{2} \text{RHO} \cdot u_0^2 \cdot \frac{\partial \text{CLA}}{\partial \theta}$$

$$Z_w = 0.5 \text{ RHO } u_0 \text{ DIFB1}$$

$$B1 = Z_w$$

where:

$$\text{CLA} = C_1 A \text{ (lift coefficient x area)}$$

$$\text{DIFB1} = \frac{\partial \text{CLA}}{\partial \theta} \text{ (DIFB1 is the symbol used in the computer program)}$$

C1

$$C1 = Z_z$$

$$Z_z = \frac{\partial Z}{\partial z} = \frac{\partial (\text{lift})}{\partial z} = \frac{1}{2} \text{RHO} \cdot u_0^2 \cdot \frac{\partial (\text{CLA})}{\partial z}$$

$$Z_z = 0.5 \text{ RHO } u_0^2 \text{ DIFC1}$$

$$C1 = Z_z$$

---

\* See Appendix B.

THE DERIVATION OF COEFFICIENTS FOR FORCE AND MOMENT EQUATIONS:

A1

A1 and A2 will have to have terms containing edged mass and edged inertia respectively. This is necessary because the edged mass and edged inertia may be of the same order of magnitude as that of the post itself.

$$A1 = W + W_{ERM}$$

B1

$$B1 = \Sigma W$$

$$\Sigma W = \frac{1}{2} \Sigma W = \frac{1}{2} \cdot \frac{60 \cdot 55}{50}$$

$$\frac{60}{50} = \frac{1}{\sqrt{2}}$$

$$\frac{60}{50} = \frac{1}{\sqrt{2}} \cdot \frac{60 \cdot 55}{50}$$

$$\Sigma W = 0.5 \cdot \frac{60 \cdot 55}{50}$$

$$B1 = \Sigma W$$

where:

$$CLA = C_1 A \text{ (lift coefficient x area)}$$

$$DIRBI = \frac{CLA}{\theta} \text{ (DIRBI is the symbol used in the computer program)}$$

C1

$$C1 = \Sigma W$$

$$\Sigma W = \frac{1}{2} \Sigma W = \frac{1}{2} \cdot \frac{60 \cdot 55}{50} \cdot \frac{60 \cdot 55}{50}$$

$$\Sigma W = 0.5 \cdot \frac{60 \cdot 55}{50} \cdot \frac{60 \cdot 55}{50}$$

$$C1 = \Sigma W$$

\* See Appendix E.

where:

DIFC1 = computer program symbol for  $\frac{\partial CLA}{\partial z}$

D1

FIGURE 1

$$D1 = Z_{\dot{q}}$$

$$Z_{\dot{q}} = \frac{\partial Z}{\partial \dot{q}}$$

$$r = \frac{VCG}{\sin \alpha}$$

Limits on  $\alpha$ :

$$\cot^{-1} \left( \frac{CG - WETL}{VCG} \right) \rightarrow \frac{\pi}{2} \rightarrow \cot^{-1} \left( \frac{CG}{VCG} \right)$$

$$\dot{v} = r \cdot \dot{q} = \frac{VCG \cdot \dot{q}}{\sin \alpha}$$

$$\dot{v}_z = \frac{VCG \cdot \dot{q} \cdot \cos(\theta + \alpha)}{\sin \alpha}$$

$$dZ = d(m \cdot \dot{w}) = \frac{\pi}{2} \cdot RHO \cdot BEAM^2 \cdot d\xi \left( \frac{VCG}{\sin \alpha} \cdot \cos(\theta + \alpha) \right) \dot{q}^*$$

$$\xi = VCG \cdot \cot \alpha$$

---

\* See reference (9), page 420, Fig. 62A.

$$d \xi = -VCG. \csc^2 a da$$

$$\frac{Z}{\dot{q}} = -\frac{\pi}{2} \cdot RHO \cdot BEAM^2 \cdot VCG^2 \int_{\xi = CG - WETL}^{\xi = CG} \frac{\cos(\theta + a) da}{\sin^3 a}$$

$$Z_{\dot{q}} = \frac{Z}{\dot{q}}$$

$$Z_{\dot{q}} = \frac{\pi}{2} \cdot RHO \cdot BEAM^2 \cdot VCG \cdot WETL \cdot \left[ \frac{\cos \theta}{VCG} \left( CG - \frac{WETL}{2} \right) - \sin \theta \right]$$

$$D1 = Z_{\dot{q}}$$

E1

FIGURE 2

$$E1 = Z_{\dot{q}} + u_0 \cdot Z_{\dot{w}}$$

$$Z_{\dot{q}} = \frac{\partial Z}{\partial q} = \frac{\partial w}{\partial q} \cdot \frac{\partial \theta}{\partial w} \cdot \frac{\partial Z}{\partial \theta} = \frac{\partial w}{\partial q} \cdot B1$$

We now wish to express q as an effective velocity, w.

$$r = \frac{VCG}{\sin a}$$

$$v = r \cdot q \cdot \cos(a + \theta) = VCG \cdot q (\cos \theta \cdot \cot a - \sin \theta)$$

d(v.a) = increment of velocity x area

$$= VCG \cdot q \cdot (\cos \theta \cdot \cot a - \sin \theta) d \xi \cdot BEAM$$

$$\bar{V} \cdot A = -VCG^2 \cdot BEAM \cdot q \cdot \left[ \cos \theta \int \cot a \cdot \csc^2 a \, da - \sin \theta \int \csc^2 a \, da \right] \left. \begin{array}{l} \xi = CG \\ \xi = CG - WETL \end{array} \right\}$$

where: A = wetted area = WETL . BEAM

$$\bar{V} \cdot A = -WETL \cdot BEAM \cdot q \cdot \left[ \cos \theta (0.5 WETL - CG) + VCG \cdot \sin \theta \right]$$

$$Z_q = B1 \left[ \cos \theta (CG - 0.5 WETL) - VCG \cdot \sin \theta \right]$$

$$E1 = Z_q + u_o \cdot VERM$$

G1

$$G1 = Z_\theta + u_o \cdot Z_w$$

$$\text{Lift} = \frac{1}{2} \cdot RHO \cdot u_o^2 \cdot CLA = Z$$

$$\frac{\partial Z}{\partial \theta} = \frac{1}{2} \cdot RHO \cdot u_o^2 \frac{\partial(CLA)}{\partial \theta}$$

$$Z_\theta = \frac{1}{2} \cdot RHO \cdot u_o^2 \text{DIFB1} = u_o \cdot B1$$

$$\begin{aligned} G1 &= Z_\theta + u_o \cdot Z_w = u_o \cdot B1 + u_o \cdot B1 \\ &= 2 \cdot u_o \cdot B1 \end{aligned}$$

$$\underline{A2} = YI + \text{VERYI}^*$$

where:

YI = pitching moment of inertia

VERYI = added inertia.

$$dM = \frac{\pi}{2} \cdot \text{RHO} \cdot \text{BEAM}^2 \cdot d\xi (\xi \cdot \cos \theta - \text{VCG} \cdot \sin \theta) \cdot \dot{w}$$

Note: Incremental force = d (added mass  $\cdot \dot{w}$ )

added mass term taken from reference (11), page 420,

Figure 62A, for an increment of length.

$$M_w = \frac{\pi}{2} \cdot \text{RHO} \cdot \text{BEAM}^2 \int_{\text{CG} - \text{WETL}}^{\text{CG}} (\xi \cdot \cos \theta - \text{VCG} \cdot \sin \theta) d\xi$$

$$= \frac{\pi}{2} \cdot \text{RHO} \cdot \text{BEAM}^2 \cdot \text{WETL} [\cos \theta (\text{CG} - .5 \text{WETL}) - \text{VCG} \cdot \sin \theta]$$

$$D2 = M_w$$

E2

FIGURE 6

$$E2 = M_w$$

$$M_w = \frac{\partial M}{\partial w} = \frac{\partial (\text{force} \cdot \text{arm})}{\partial w}$$

$$= \text{arm} \frac{\partial (\text{force})}{\partial w} + \text{force} \frac{\partial (\text{arm})}{\partial w}$$

$$= [(\text{CG} - \text{CPL}) \cos \theta - \text{VCG} \cdot \sin \theta] \frac{\partial (\text{lift})}{\partial w}$$

$$M_w = [(\text{CG} - \text{CPL}) \cos \theta - \text{VCG} \cdot \sin \theta] B1$$

$$E2 = M_w$$

G2

See Figure 4.

$$G2 = M_z$$

$$M_z = \frac{\partial M}{\partial z} = \frac{\partial(\text{force, arm})}{\partial z}$$

$$= \text{force} \frac{\partial(\text{arm})}{\partial z} + \text{arm} \frac{\partial(\text{force})}{\partial z}$$

$$\frac{\partial(\text{arm})}{\partial z} = -\cos \theta \frac{\partial(\text{CPL})}{\partial z}$$

assuming:  $\text{CPL} \approx C_1 \cdot \text{WK}$

where  $C_1$  is an arbitrary coefficient.

$$\text{WK} = \frac{H}{\sin \theta}$$

where  $H$  = draft at transom.

$$\frac{\partial(\text{WK})}{\partial z} = \frac{1}{\sin \theta} \frac{\partial H}{\partial z} = \frac{1}{\sin \theta}$$

$$\begin{aligned} \frac{\partial(\text{arm})}{\partial z} &= -\frac{\cos \theta}{\sin \theta} C_1 = -C_1 \cot \theta \\ &= -\frac{\text{CPL}}{\text{WK}} \cot \theta \end{aligned}$$

$$M_z = [(\text{CG} - \text{CPL}) \cos \theta - \text{VCG} \sin \theta] C_1 - W \frac{\text{CPL}}{\text{WK}} \cot \theta$$

$$G2 = M_z$$

Note: Computer program determines  $\frac{\partial(\text{arm})}{\partial z}$  by incrementing variables

$$\text{in the equation } \text{CPL} = 0.75 - \frac{1}{5.21\left(\frac{v}{\lambda}\right)^2 + 2.39}$$

developed in reference (10), page 16.

G2

See Figure 4.

$$G2 = M_s$$

$$M_s = \frac{0.16}{0.2} = \frac{5(\text{force arm})}{0.2}$$

$$\text{force} = \frac{5(\text{arm})}{0.2} + \frac{5(\text{force})}{0.2}$$

$$\frac{5(\text{arm})}{0.2} = -\cos \theta \frac{5(\text{CPL})}{0.2}$$

$$\text{assumes: CPL} = C_1 \cdot WK$$

where  $C_1$  is an arbitrary coefficient.

$$WK = \frac{H}{\sin \theta}$$

where  $H$  = draft at transom.

$$\frac{1(WK)}{0.2} = \frac{1}{\sin \theta} \frac{0.16}{0.2} = \frac{1}{\sin \theta}$$

$$\frac{5(\text{arm})}{0.2} = -\frac{\cos \theta}{\sin \theta} C_1 = -C_1 \cot \theta$$

$$= -\frac{\text{CPL}}{WK} \cot \theta$$

$$M_s = (CG - CPL) \cos \theta - \sqrt{CG \sin \theta} \frac{1}{C_1} = W \frac{\text{CPL}}{WK} \cot \theta$$

$$G2 = M_s$$

Note: Computer program determines  $\frac{5(\text{arm})}{0.2}$  by incrementing variables

$$\text{in the equation } CPL = 0.15 \frac{1}{C_1} \quad 2.21 \left(\frac{1}{\lambda}\right)^2 = 2.10$$

developed in reference (10), page 16.

APPENDIX B

Solving for Added Mass:

Because of a lack of information about deadrise surfaces the added mass is calculated as for a submerged elliptic cylinder. The result will be divided in half and the minor axes of the ellipse will be set to zero. This is assumed to be a suitable approximation of the added mass of a deadrise hull at the water surface.

For flow past an elliptic cylinder (page 251, (8):

$$w = \frac{A}{\zeta} + \frac{B}{\zeta^2}$$

where:  $w$  = complex potential  
 $\zeta = e^{i\eta}$ , a unit circle  
 $A = U (b \cos \alpha + i a \sin \alpha)$   
 $B = \frac{i}{4} \omega (a^2 - b^2)$

For the case in question where only the vertical oscillation is being considered,

$$\omega = 0$$

so:  $w = \frac{A}{\zeta} = \frac{U (b \cos \alpha + i a \sin \alpha)}{\zeta}$   
 $\bar{w} = \bar{A} \zeta$

$$\frac{d\bar{w}}{d\zeta} = \bar{A}$$

Now:  $T = - \frac{1}{4} i \rho \int_{(c)} \frac{A\bar{A}}{\zeta} d\zeta$   $T = \text{kinetic energy}$   
 $= - \frac{1}{4} i \rho [2 \pi i (\text{the residue } A\bar{A})]$   
 $= - \frac{1}{4} i \rho 2\pi i U^2 (b^2 \cos^2 \alpha + a^2 \sin^2 \alpha)$

For this case  $\alpha = 90^\circ$ ,  $b = 0$  and  $T = \frac{U^2}{2} \rho \pi a^2$

but  $T = \frac{1}{2} M U^2$

then  $2 \text{ VERM} = \rho \pi a^2$  per unit width

and  $\text{VERM} = \frac{\rho \pi}{2} (\text{WETL})^2 (\text{BEAM})$

APPENDIX B

Solving for Added Mass:

Because of a lack of information about behavior between the added mass is calculated as for a submerged elliptic cylinder. The result will be divided in half and the minor axis of the ellipse will be set to zero. This is assumed to be a suitable approximation of the added mass of a binnacle hull at the water surface.

For flow past an elliptic cylinder (page 251, 197):

$$w = \frac{A}{z} + \frac{B}{\bar{z}}$$

where:  $w$  = complex potential

$z = re^{i\theta}$ ,  $\bar{z}$  = unit circle

$A = U(p \cos \alpha + i a \sin \alpha)$

$B = \frac{i}{4} \omega (a^2 - b^2)$

For the case in question where only the vertical oscillation is being

considered,

$$\omega = 0$$

$$w = \frac{A}{z} = \frac{U(p \cos \alpha + i a \sin \alpha)}{z}$$

$$w = \frac{A}{z}$$

$$\frac{dw}{dz} = \frac{A}{z^2}$$

Now:  $T = \frac{1}{4} \rho \int_0^{2\pi} r^2 \left( \frac{dw}{dz} \right)^2 dz$   $T = \text{kinetic energy}$

$$= \frac{1}{4} \rho \int_0^{2\pi} r^2 \left( \frac{A}{z^2} \right)^2 dz$$

$$= \frac{1}{4} \rho \int_0^{2\pi} U^2 (p \cos \alpha + i a \sin \alpha)^2 dz$$

For this case  $\alpha = 90^\circ$ ,  $b = 0$  and  $T = \frac{1}{2} \rho \pi a^2$

$$\text{but } T = \frac{1}{2} M U^2$$

then  $M = \rho \pi a^2$  per unit width

$$\text{and } \text{VERM} = \frac{\rho \pi}{2} (\text{WELL})^2 (\text{BEAM})$$

The Added Inertia:

The problem here is to determine the added inertia for a body rotating about some point other than its center.

For rotation about a point other than the center of the body the complex potential is given by:

$$w - i \omega Z_0 \bar{Z}$$

In this case  $Z_0 = \bar{Z}$  because it is on the real axis.

$$Z = a \cos \eta + i b \sin \eta$$

then

$$w = \frac{A}{\zeta} + \frac{B}{\zeta^2} - i \omega Z_0 (a \cos \eta + i b \sin \eta)$$

$$\bar{w} = \bar{A}\zeta + \bar{B}\zeta^2 + i \omega Z_0 a \cos \eta + b \omega Z_0 \sin \eta$$

$$\frac{d\bar{w}}{d\zeta} = \bar{A} + 2\bar{B}\zeta - i \omega Z_0 a \sin \eta \frac{d\eta}{d\zeta} + b \omega Z_0 \cos \eta \frac{d\eta}{d\zeta}$$

$$\zeta = e^{i\eta}$$

$$\frac{d\zeta}{d\eta} = i e^{i\eta} = \frac{1}{i\zeta}$$

$$\frac{d\bar{w}}{d\zeta} = \bar{A} + 2\bar{B}\zeta + \frac{\omega Z_0}{\zeta} \left( \frac{1}{i} b \cos \eta - a \sin \eta \right)$$

$$w d\bar{w} = \frac{A\bar{A}}{\zeta} + \frac{\bar{A}B}{\zeta^2} - i \bar{A} \omega Z_0 (a \cos \eta + i b \sin \eta)$$

$$+ 2 \bar{B}A + \frac{2\bar{B}B}{\zeta} - i 2 \bar{B}\zeta \omega Z_0 (a \cos \eta + i b \sin \eta)$$

$$- \frac{i\omega^2 Z_0^2}{\zeta} (a \cos \eta + i b \sin \eta) \left( \frac{1}{i} b \cos \eta - a \sin \eta \right)$$

$$T = - \frac{1}{4} i \rho \int w d\bar{w}$$

$$= - \frac{1}{4} i \rho \left[ \int_{(c)} \frac{\bar{A}A}{\zeta} + 2 \frac{\bar{B}B}{\zeta} + 2 \bar{B}A + \frac{AB}{\zeta^2} d\zeta \right.$$

$$+ \int_{(c)} - \frac{i\omega Z_0^2}{\zeta} (a \cos \eta + i b \sin \eta) \left( \frac{1}{i} b \cos \eta - a \sin \eta \right) d\zeta$$

$$+ \int_{(c)} - i \bar{A} \omega Z_0 (a \cos \eta + i b \sin \eta) d\zeta$$

$$\left. + \int_{(c)} - i 2 \bar{B}\zeta \omega Z_0 (a \cos \eta + i b \sin \eta) d\zeta \right]$$

$$= F1 + F2 + F3 + F4$$

The Adjoint Invariant:

The problem here is to determine the adjoint invariants for a body rotating about some point other than its center.

For rotation about a point other than the center of the body the complex potential is given by:

$$w = z - i\omega \bar{z}$$

In this case  $\bar{z} = \bar{z}$  because it is on the real axis.

$$\bar{z} = a \cos \theta + i b \sin \theta$$

then

$$w = \frac{z}{2} + \frac{\bar{z}}{2} - i\omega z (a \cos \theta + i b \sin \theta)$$

$$\bar{w} = \frac{\bar{z}}{2} + \frac{z}{2} - i\omega \bar{z} (a \cos \theta + i b \sin \theta)$$

$$\frac{dw}{dz} = \frac{1}{2} + \frac{1}{2} \bar{z} - i\omega (a \cos \theta + i b \sin \theta) + \frac{d\bar{z}}{dz} (a \cos \theta + i b \sin \theta)$$

$$\bar{z} = a \cos \theta$$

$$\frac{d\bar{z}}{dz} = i a \sin \theta = \frac{1}{2}$$

$$\frac{dw}{dz} = \frac{1}{2} + \frac{1}{2} \bar{z} - i\omega (a \cos \theta + i b \sin \theta) + \frac{1}{2} (a \cos \theta + i b \sin \theta)$$

$$w \bar{w} = \frac{\bar{A}\bar{A}}{2} + \frac{\bar{A}B}{2} - i\omega \bar{z} (a \cos \theta + i b \sin \theta)$$

$$+ \frac{2\bar{B}A}{2} + \frac{2\bar{B}B}{2} - i\omega \bar{z} (a \cos \theta + i b \sin \theta)$$

$$- \frac{1}{2} (a \cos \theta + i b \sin \theta) (a \cos \theta + i b \sin \theta) + \frac{1}{2} (a \cos \theta + i b \sin \theta)$$

$$T = -\frac{1}{4} i \rho (w \bar{w})$$

$$= -\frac{1}{4} i \rho \left[ \frac{\bar{A}\bar{A}}{2} + \frac{\bar{A}B}{2} + \frac{2\bar{B}A}{2} + \frac{2\bar{B}B}{2} + \frac{AB}{2} \right]$$

$$+ \left[ \frac{1}{2} (a \cos \theta + i b \sin \theta) (a \cos \theta + i b \sin \theta) + \frac{1}{2} (a \cos \theta + i b \sin \theta) \right] \rho$$

$$+ \left[ -i\omega \bar{z} (a \cos \theta + i b \sin \theta) \right] \rho$$

$$- \left[ -i\omega \bar{z} (a \cos \theta + i b \sin \theta) \right] \rho$$

$$= \rho \left[ \frac{1}{4} (\bar{A}\bar{A} + \bar{A}B + 2\bar{B}A + 2\bar{B}B + AB) \right]$$

$$F1 = 2 \pi i (A\bar{A} + 2 B\bar{B})$$

$$F2 = 2 \pi i \omega^2 Z_0^2 a b + \int \frac{i (b^2 - a^2) \sin 2 \eta}{\mathcal{J}} \frac{d\mathcal{J}}{2} d\mathcal{J}$$

but  $\mathcal{J} = e^{i\eta}$

$$d\mathcal{J} = i e^{i\eta} d\eta$$

Limits:  $0 \rightarrow 2\pi$

$$F2 = 2 \pi i \omega^2 Z_0^2 a b + \int_0^{2\pi} i \frac{(b^2 - a^2) \sin 2 \eta}{e^{i\eta}} \frac{e^{i\eta}}{2} d\eta$$

$$F2 = 2 \pi i \omega^2 Z_0^2 a b.$$

$$F3 = i \bar{A} \omega Z_0 \int_0^{2\pi} (a \cos \eta + i b \sin \eta) (\cos \eta + i \sin \eta) d\eta$$

$$= i \pi \bar{A} \omega Z_0 (a - b)$$

$$F4 = -i 2\bar{B} \omega Z_0 \int_0^{2\pi} (a \cos \eta + i b \sin \eta) (\cos 2 \eta + i \sin 2 \eta) d\eta$$

$$= -i 2\bar{B} \omega Z_0 (0)$$

$$= 0$$

$$T = -\frac{1}{4} i \int \rho w d\bar{w}$$

$$= -\frac{1}{4} i \rho (2 \pi i (A\bar{A} + 2 B\bar{B}) + 2 \pi i \omega^2 Z_0^2 a b + \pi i \bar{A} \omega Z_0 (a - b))$$

In this case  $A = \bar{A} = 0$  because there is no Z translation.

Therefore:

$$T = -\frac{1}{4} i \rho (2 \pi i (2 B\bar{B}) + 2 \pi i \omega^2 Z_0^2 a b)$$

$$= \frac{\rho \pi}{2} (2 \omega^2 (a^2 + b^2) + \omega^2 Z_0^2 a b)$$

for the plate,  $b = 0$

$$\text{so } T = \frac{\rho \pi}{16} \omega^2 a^4$$

$$\text{VERYI} = \frac{1}{8} \pi \rho a^4 \text{ per unit width}$$

$$= \frac{1}{8} \pi \rho (\text{WETL})^4 \text{ BEAM.}$$

$$F_1 = 2\omega(A\bar{A} + B\bar{B})$$

$$F_2 = 2\omega^2 \left( \frac{A^2 + B^2}{2} + i \frac{A^2 - B^2}{2} \right)$$

but  $T = 0$

$$F_2 = 2\omega^2 \frac{A^2 + B^2}{2}$$

$$F_3 = 2\omega^2 \left( \frac{A^2 + B^2}{2} + i \frac{A^2 - B^2}{2} \right)$$

$$F_3 = 2\omega^2 \frac{A^2 + B^2}{2}$$

$$F_3 = i \bar{A} \omega \Sigma (a \cos \theta + i b \sin \theta) (2\omega^2 + i \sin \theta) \Sigma$$

$$= i \bar{A} \omega \Sigma (a - b)$$

$$F_4 = -i \bar{B} \omega \Sigma (A \cos \theta + i B \sin \theta) (2\omega^2 + i \sin \theta) \Sigma$$

$$= -i \bar{B} \omega \Sigma (a)$$

$$T = \frac{1}{2} \left( \dots \right)$$

$$= \frac{1}{2} \left( i \bar{A} \omega \Sigma (a - b) + i \bar{B} \omega \Sigma (a) + \bar{A} \bar{B} \Sigma (a + i b) \right)$$

In this case  $A = \bar{A} = 0$  because there is no translation.

Therefore:

$$T = -\frac{1}{2} \left( 2\omega^2 \bar{B} \Sigma (a) + 2\omega^2 \bar{A} \Sigma (a) \right)$$

$$= \frac{\omega^2}{2} (2\omega^2 (a^2 + b^2) + \omega^2 \Sigma (a))$$

for the given  $b = 0$

$$\text{so } T = \frac{\omega^2}{2} a^2$$

$$\text{VERIFY } = \frac{1}{2} \omega^2 a^2 \text{ for our system}$$

$$= \frac{1}{2} \omega^2 a^2 \text{ (verified)}$$

APPENDIX C.

From Figure 16 of (12) the stability of a planing craft can be increased by increasing

$$\sqrt{\frac{C_L}{2}} \text{ i.e. } C_L.$$

But  $C_L = .0120 \lambda^{1/2} \tau^{1.1}$  (page 10, (12))

Since increasing  $C_L$  increases stability, increasing  $\lambda$  increases stability.

In this case  $\lambda = \frac{1 m}{b}$ . This means that a decrease in  $b$  will result in an increase in stability.

From Figure 20 of (2) the stability criterion is

$$\frac{C_{Lb}}{l_{cp}/b} = \frac{1.80}{(F_{\nabla})^{2.5}}$$

where:

$$C_{Lb} = \frac{W}{\frac{1}{2} \rho V^2 b^2}$$

and:

$$F = \left( \frac{V}{g \nabla^{1/3}} \right)^2$$

If  $\frac{C_{Lb}}{l_{cp}/b} = \frac{W}{\frac{1}{2} \rho V^2 b^2 l_{cp}}$  decreases, the boat

is stabilized. Therefore increasing  $b$  stabilizes the boat.

A comparison of the two methods makes it difficult to decide what effect  $b$  has on stability.

From Figure 18 of (12) the stability of a damping effect can be increased by increasing

But  $C_L = 0.020 \times \sqrt{1.1}$  (page 10, (12))

$$\sqrt{\frac{C_L}{2}} \text{ i. e. } \sqrt{\frac{0.020 \times 1.1}{2}}$$

Since increasing  $C_L$  increases stability, increasing  $\Delta$  increases stability. In this case  $\Delta = \frac{1}{p}$ . This means that a decrease in  $p$  will result in an increase in stability.

From Figure 20 of (2) the stability criterion is

$$\frac{C_{Lb}}{1 \text{ cp} \sqrt{2}} = \frac{1.20}{(FV) \sqrt{2}}$$

where:

$$C_{Lb} = \frac{W}{\frac{1}{2} \rho V^2 D^2}$$

and:

$$F = \left( \frac{V}{1} \right) \frac{1}{\sqrt{2}}$$

If  $\frac{C_{Lb}}{1 \text{ cp} \sqrt{2}} = \frac{W}{\frac{1}{2} \rho V^2 D^2}$  decreases the best

is stabilized. Therefore increasing  $p$  stabilizes the best.

A comparison of the two methods makes it difficult to decide what effect  $p$  has on stability.

APPENDIX D.

In order to determine the resistance of a planing surface it is necessary to know the mean velocity over the bottom.

In Figure 12 of (12) a method is provided for determining this graphically. Part of an analytic solution is provided which, if completed, would be useful in the computation of mean velocity in a computer program.

The following is a resume of the development of the complete equation.

From (12):

$$\frac{VM}{V} = \sqrt{1. - \frac{0.0120 \tau^{1.1}}{\lambda \frac{1}{2} \cos \tau} f(\beta)}$$

where:

VM = mean velocity over bottom (fps)

V = the  $u_0$ , the horizontal velocity of the origin of coordinates (fps)

$\tau$  = trim angle of planing surface (degrees)

$f(\beta)$  = an undetermined function.

By changing  $\tau$  to radians and plotting

$$\left[ 1 - \left( \frac{VM}{V} \right)^2 \right] \frac{\lambda \frac{1}{2} \cos \tau}{.0120 \tau^{1.1}} = f(\beta)$$

it was possible to find an  $f(\beta)$  which yielded satisfactory results.

The final result is:

$$\frac{VM}{V} = \sqrt{1. - \frac{0.120 \tau^{1.1}}{\lambda \frac{1}{2} \cos \tau} \cdot \frac{80. - 50. \beta}{\cos^2 \beta}}$$

where:

$$f(\beta) = \frac{80. - 50. \beta}{\cos^2 \beta}$$

$\tau$  = trim angle in radians

$\beta$  = deadrise angle in radians.

APPENDIX II

In order to determine the position of a pinning contact it is necessary to know the mean velocity over the bottom

In Figure 11 of (1) a formula is provided for determining this velocity. Part of an analytic solution is provided which, if completed, would be useful in the computation of mean velocity in a computer program.

The following is a resume of the development of the complete equation.

From (1):

$$\frac{VM}{V} = \sqrt{1 - \frac{0.0120 \tau^{1.1}}{\frac{1}{2} \cos \tau}} \quad (1)$$

where:

VM = mean velocity over bottom (fps)

V = 32.2 ft/sec, the horizontal velocity of the origin of coordinates (fps)

$\tau$  = trim angle of pinning contact (degrees)

(1) = an undetermined function.

By changing to radians and putting

$$[1 - \left(\frac{VM}{V}\right)^2] \frac{1}{2} \cos \tau = \frac{0.0120 \tau^{1.1}}{1} \quad (2)$$

It was possible to find an (2) which yielded satisfactory results.

The final result is:

$$\frac{VM}{V} = \sqrt{1 - \frac{0.0120 \tau^{1.1}}{\frac{1}{2} \cos \tau}} \quad (3)$$

where:

$$(3) = \frac{50.4 - 50.4}{\cos \tau}$$

$\tau$  = trim angle in radians

$\tau$  = trim angle in radians

⊙ INDICATES CALCULATED VALUES

Figure 7.

VM/V vs.  $\lambda$  from Figure 12 of Reference 12 compared with Values Calculated using the Empirical Function  $f(\beta)$ .

APPENDIX E.

EQUILIBRIUM PLANING CONDITIONS.

FIGURE 8

Note: This development follows reference (12) in general. However, the final result contains terms neglected by SAVITSKY.

Summation of forces in vertical direction:

$$(1) W = N \cdot \cos \theta + T \cdot \sin (\theta + \epsilon) - D_f \cdot \sin \theta$$

Summation of pitching moments:

$$(2) N \cdot c + D_f \cdot a - T \cdot f = 0$$

Summation of forces along keel:

$$(3) T \cdot \cos \epsilon = D_f + W \cdot \sin \theta$$

Combining (1) and (3):

$$(4) N = \frac{W}{\cos \theta \cdot \cos \epsilon} \left[ \cos \epsilon - \sin \theta \cdot \sin (\theta + \epsilon) \right] + \frac{D_f}{\cos \theta \cdot \cos \epsilon} \cdot \left[ \sin \theta \cdot \cos \epsilon - \sin (\theta + \epsilon) \right]$$

Combining (2) and (3):

$$(5) N \cdot c + D_f \cdot a - \frac{f}{\cos \epsilon} [W \cdot \sin \theta + D_f] = 0$$

Combining (4) and (5), we obtain the general equilibrium requirement:

$$W \left[ \frac{[\cos \epsilon - \sin \theta \sin (\theta + \epsilon)] c}{\cos \theta \cdot \cos \epsilon} - \frac{f \cdot \sin \theta}{\cos \epsilon} \right] + D_f \left[ \frac{[\sin \theta \cos \epsilon - \sin (\theta + \epsilon)] c + a}{\cos \theta \cos \epsilon} - \frac{f}{\cos \epsilon} \right] = 0$$

Equations (1) and (2)

$$(3) \quad a \cdot \cos \theta = b \cdot \sin \theta + c \quad \left[ \frac{1}{\cos \theta} \right]$$

Combining (1) and (3), we obtain the general following relationship:

$$W \left[ \frac{a \cos \theta - b \sin \theta - c}{\cos \theta} \right]$$

$$= \left[ \frac{a \cos \theta - b \sin \theta - c}{\cos \theta} \right] + D$$

COMPUTER PROGRAMS

PROGRAM 1

Program 1 can be used to solve for the stability derivatives, coefficients of the equations of motion, the coefficients of the characteristic equation and the Routh discriminant using experimental data as input.

Data cards are punched in the manner indicated by READ 1 and 1 FORMAT where:

W	weight of boat in (lbs)
ALFAO	trim angle when boat is at rest (degrees)
CG	longitudinal position of center of gravity forward of transom (ft)
C	forward speed (knts)
RT	towing force (lbs)
WK	wetted length of keel (ft)
WC	wetted length of chine (ft)
S	wetted area (ft <sup>2</sup> )
TRIM	(planing angle - $\alpha_0$ ) (degrees) is change of trim from the at rest position
YI	moment of inertia about the Y-axis. Axis taken through center of gravity. (lb ft sec <sup>2</sup> )
RHO	density of water (lb sec <sup>2</sup> /ft)
U	arbitrary non dimensionalizing velocity (ft/sec)
BEAM	beam of boat (ft)
BETAI	deadrise angle (degrees)
VCG	height of center of gravity above the keel (ft)
EPSIL	shaft angle (degrees).

Equation 1 can be used to solve for the stability derivatives, coefficients of the equations of motion, the coefficients of the characteristic equation and the roots, distribution using experimental data as input.

Data cards are punched in the manner indicated by READ 1 and

1 FORMAT where:

W	weight of boat (lbf)

PROGRAM 2.

This program solves for planing conditions: TRIM, ASPECT RATIO, WETTED KEEL, WETTED CHINE, WETTED AREA, DRAG, DRAFT at the transom, MEAN WETTED LENGTH, ESTIMATED EHP and the STABILITY INDICATOR (Routh discriminant: positive indicators imply stability, negative indicators imply instability. This section of the program does not yield satisfactory results as yet.)

A listing of all iterations involved in solving for the planing conditions and a listing of the coefficients of the equations of motion can be obtained as indicated by comments on the first page of the program print out.

This program uses as input, 1st card:

LIST 1, LIST 2, N BOATS

FORMAT (3 I 3).

LIST 1 and LIST 2 are as defined on first page of the program print out.

N BOATS is the number of different boats to be run.

2nd card:

BETA1, EPSILI, F, VCG, BEAM, CG, RHO, YI, W

FORMAT (4 F 5.2, 5 F 10.2)

BETA1 = BETA of PROGRAM 1

EPSILI = EPSIL of PROGRAM 1

F is the perpendicular distance from shaft center line to CG (ft).  
All other variables are as defined on page 58.

3rd card:

NUMBER, IDENT

FORMAT (I 3, 5A4)

NUMBER = number of speed cards which are to follow

IDENT any identifying statement or symbol not to exceed 20 spaces.

SECTION 1

The program is for... (text is mirrored and difficult to read)

A listing of all... (text is mirrored and difficult to read)

This program uses as input...  
LIST 1, LIST 2, N BOATS  
FORMAT (1, 2)

LIST 1 and LIST 2 are defined on first page of the program print  
out.  
N BOATS is the number of different boats to be run.

2nd card:  
BREAL, BREAL, F, W, B, BEAM, CG, SW, VL, W  
FORMAT (E, F, 2, 2, F, 10, 2)  
BREAL - BREAL of PROGRAM 1  
BREAL - BREAL of PROGRAM 1

F is the perpendicular distance from shaft center line to CG (ft).  
All other variables are as defined on page 58.

3rd card:  
NUMBER IDENT  
FORMAT (1, 2, 3)

NUMBER = number of speed cards which are to follow  
IDENT = any identifying symbol or symbol not to exceed 20 spaces.

4th card:

VKTS

FORMAT (F 10.2)

VKTS is velocity of boat in knots. One card is required for each speed. Number of cards equals NUMBER on card 3.
